

# HW3 Report

## Section 1

Q1:

Figure 1: KDE plots of `VirusScore` conditioned different conditions of `blood_type`

Q2:

In figure 1 in the plot of A versus not A, we observe that the groups of patients with and without "A" in their blood types are mostly separable along a boundary that is approximately the `VirusScore` of 0.225.

Therefore, the condition of contains/does not contain A would be most informative for learning `VirusScore`. As it turns out, we decided already in hw1 to create this feature.

Q3:

$$\begin{aligned}
\frac{\partial}{\partial b} \mathcal{L}(\mathbf{w}, b) &\stackrel{a}{=} \frac{\partial}{\partial b} \frac{1}{m} \sum_{i=1}^m (\mathbf{w}^\top \mathbf{x}_i + b - y_i)^2 \stackrel{b}{=} \frac{1}{m} \frac{\partial}{\partial b} \sum_{i=1}^m (\mathbf{w}^\top \mathbf{x}_i + b - y_i)^2 \stackrel{c}{=} \frac{1}{m} \sum_{i=1}^m \frac{\partial}{\partial b} (\mathbf{w}^\top \mathbf{x}_i + b - y_i)^2 \stackrel{d}{=} \\
&\stackrel{d}{=} \frac{1}{m} \sum_{i=1}^m 2 (\mathbf{w}^\top \mathbf{x}_i + b - y_i) \cdot (1) \stackrel{e}{=} \frac{2}{m} \sum_{i=1}^m (\mathbf{w}^\top \mathbf{x}_i + b - y_i) \stackrel{f}{=} \frac{2}{m} \left[ mb + \sum_{i=1}^m (\mathbf{w}^\top \mathbf{x}_i - y_i) \right] \stackrel{g}{=} \\
&\stackrel{g}{=} 2b + \frac{2}{m} \sum_{i=1}^m (\mathbf{w}^\top \mathbf{x}_i - y_i) \Rightarrow \frac{\partial}{\partial b} \mathcal{L}(\mathbf{w}, b) = 2b + \frac{2}{m} \sum_{i=1}^m (\mathbf{w}^\top \mathbf{x}_i - y_i)
\end{aligned}$$

$a$  : Definition of  $\mathcal{L}(\mathbf{w}, b)$

$b$  :  $\frac{1}{m}$  is scalar

$c$  : Derivative of a sum is the sum of derivatives

$d$  : Derivative of  $(\mathbf{w}^\top \mathbf{x}_i + b - y_i)^2$  w.r.t  $b$

$e$  : 2 is scalar

$f$  : Sum of  $b$

$g$  : Removing  $b$  from the sum

Q4:

### Residuals of analytical and numerical gradients

Figure 2: Plot of Residuals of analytical and numerical gradients

As we can see in figure 2, the difference between the analytic and numerical gradients increases in a monotonic fashion as the value of  $\delta$  increases. This is logical, as  $\delta$  is the differential size used in the definition of the numerical gradient, and therefore a smaller  $\delta$  equates to a more precise estimation of the analytic gradient by the numerical gradient.

Q5:

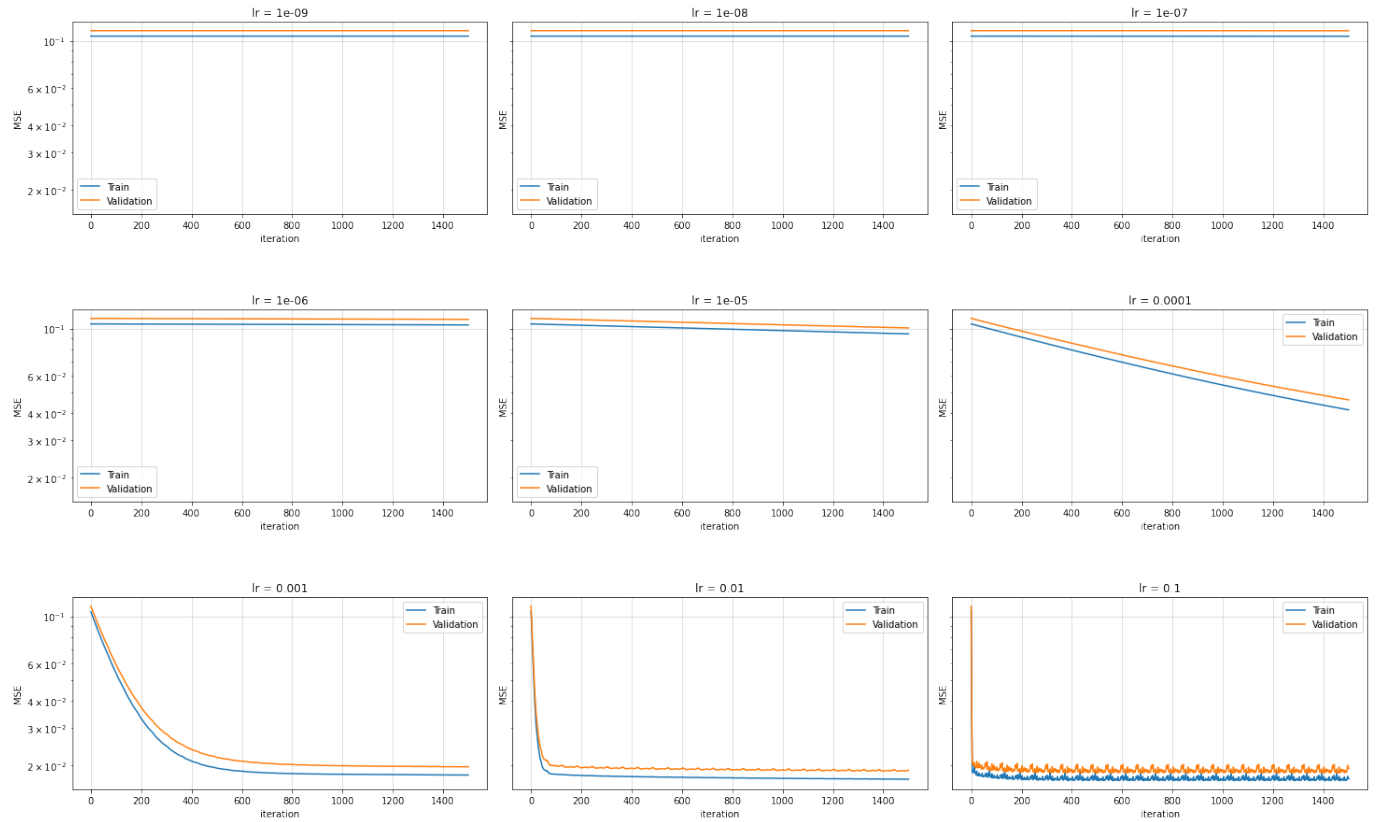

Figure 3: Graphs of Training and Validation Losses as Functions of Iteration Number for Different Learning Rates

We can see in figure 3 that for smaller  $lr$ , for those that converge, the convergence is at a higher loss for both the training and validation. This matches the theory, since if the  $lr$  is too small, the SGD algorithm is likely to converge to a sub-optimal solution. In addition we observe that for the  $lr$  equal to 0.1 the graphs do not converge for both training and validation losses and for  $lr$  equal to 0.01 the validation loss does not converge, which fits the theory that says that learning rates that are too high are likely to cause the SGD algorithm to take steps that are too large and thus repeatedly skip-over the optimal solution. This points to 0.001 as being the optimal  $lr$ , as both the validation and training losses converge to values that are substantially lower than the next smaller  $lr$ .
